CONVERSION FACTORS

For use of those readers who may prefer to use metric units rather than inch-pound units, the conversion factors for the terms used in this report are listed below.

Multiply inch-pound units	By	To obtain SI units
inch (in.)	2.540	centimeter (cm)
foot (ft)	0.305	meter (m)
mile (mi)	1.609	kilometer (km)
gallon (gal)	3.785	liter (L)
square mile (mi^2)	2.590	square kilometer (km^2)
acre	4.047×10^{-3}	square kilometer (km^2)
acre-foot (acre-ft)	1233	cubic meter (m^3)

HYDROGEOLOGIC DATA FOR THE MISSISSIPPI EMBAYMENT OF SOUTHEASTERN MISSOURI

By Richard R. Luckey and Dale L. Fuller

ABSTRACT

The Mississippi embayment of southeastern Missouri is a 4,000 square mile agricultural area that is presently (1979) undergoing rapid development for irrigation. In July 1974 a project was initiated to evaluate the water resources of the area, determine the extent of irrigation, and assess the future potential for irrigation supplies.

This report provides well drillers, well owners, water users, and potential irrigators with the basic hydrologic data collected during the project. The 10 tables and eight figures show the location of irrigation wells, water-level networks to monitor ground-water and surface-water conditions, a pumpage network to estimate amounts of water used for irrigation, geologic data, municipal-well data, and water-quality data for selected wells.

INTRODUCTION

The Mississippi embayment, which includes 4,000 mi^2 of the Southeastern Lowlands of Missouri, is an area of low-lying land in the extreme southeastern corner of the State. The area is bounded on the north and west by a northeast-trending escarpment passing through the cities of Poplar Bluff and Cape Girardeau, on the east by the Mississippi River, and on the south by the State of Arkansas. This region is an intensely developed agricultural area that provides 15 percent of the agricultural crop output of Missouri. Because of the increasing investment required to produce a crop, many farmers in the region have installed irrigation systems to increase their crop production and decrease the risk of crop failure due to insufficient rainfall.

To accommodate the need for detailed hydrologic information, the Missouri Department of Natural Resources, Division of Geology and Land Survey (formerly the Missouri Geological Survey and Water Resources) and the U.S. Geological Survey began a cooperative project in July 1974. The primary purposes of the project were to evaluate the water resources, determine the present extent of irrigation, and assess the potential of the area for further development.

PURPOSE AND SCOPE

The purpose of this report is to provide well owners, well drillers, water users, and other interested people with the hydrologic data that were collected during the course of this project. This report also briefly describes how some of the data were collected and how it can be used. The hydrology of the area will be described in a subsequent report.

Additional hydrologic data for the area can be found in the annual data reports of the U.S. Geological Survey. The latest report currently (1979) available is "Water-Resources Data for Missouri, Water Year 1978." This report gives physical, chemical, biological, and flow data at selected sites in the surface-water system. Data on the Black River, the St. Francis River, the Castor River, the Little River drainage system, the Headwater diversion channel, and the Mississippi River are given in this report.

LOCATION SYSTEM

The sites or points in ditches described in this report are identified by two systems: (1) the land-subdivision system, and (2) a unique identifying number. Measurements of water levels at selected points in ditches are also identified by the latitude and longitude of the site.

The land-net location system, referrred to in tables as "Well Location," or "Location," is based on the U.S. Bureau of Land Management system of land subdivision and locates the site to a 10-acre tract. The locations are described proceeding from the largest to the smallest subdivision.

The entire State of Missouri is governed by the Fifth Principal Meridian Survey, which subdivides the State every 6 mi in the north-south direction into townships and every 6 mi in the east-west direction into ranges (fig. 1). The first part of the location gives the number of townships north of the baseline and the second part of the location gives the number of ranges east of the Fifth Principal Meridian.

The 36-mi^2 area described by a township and range designation is further subdivided into 1-mi^2 areas called sections. The sections are numbered sequentially from 1 to 36, as shown in figure 1. The first two digits of the third part of the location designates the section number.

The section, which contains 1 mi^2 or 640 acres, is subdivided into quarter sections. This 160-acre area is designated by the first letter following the section number; A indicates the northeast quarter, B the northwest, C the southwest, and D the southeast. The quarter section is further subdivided into quarter-quarter sections. This 40-acre area is designated by the second letter following the section in the same manner. The quarter-quarter section is further subdivided into quarter-quarter-quarter sections. This 10-acre area is designated in the same manner by the third letter following the section.

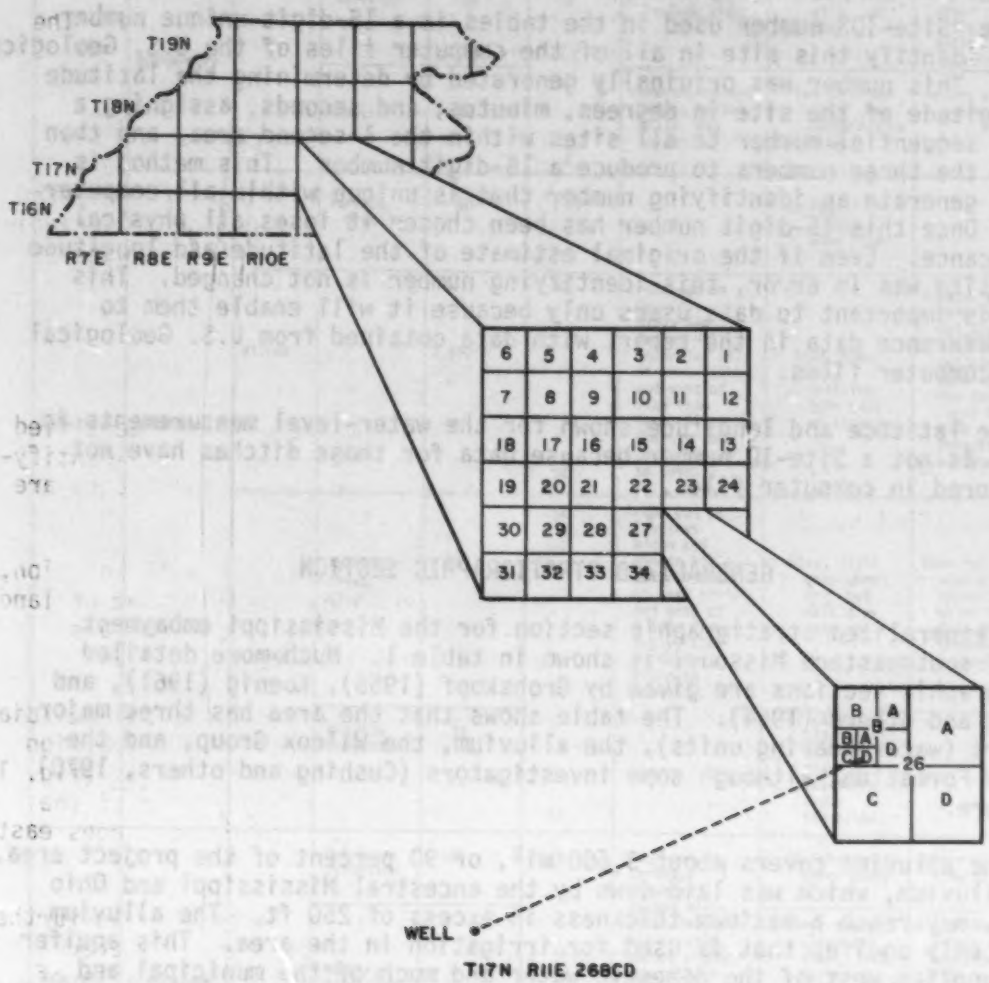

Figure 1.-- Location system based on land subdivision.

Within the 10-acre quarter-quarter-quarter section, wells are numbered sequentially in the order in which they were originally inventoried. This sequential number follows the three-letter quarter-quarter-quarter section designation.

The "Site-ID" number used in the tables is a 15-digit unique number used to identify this site in all of the computer files of the U.S. Geological Survey. This number was originally generated by determining the latitude and longitude of the site in degrees, minutes, and seconds, assigning a 2-digit sequential number to all sites within the 1-second area, and then linking the three numbers to produce a 15-digit number. This method is used to generate an identifying number that is unique within all computer files. Once this 15-digit number has been chosen it loses all physical significance. Even if the original estimate of the latitude and longitude of the site was in error, this identifying number is not changed. This number is important to data users only because it will enable them to cross-reference data in the report with data obtained from U.S. Geological Survey computer files.

The latitude and longitude shown for the water-level measurements in ditches is not a Site-ID number because data for those ditches have not been stored in computer files.

GENERALIZED STRATIGRAPHIC SECTION

A generalized stratigraphic section for the Mississippi embayment area of southeastern Missouri is shown in table 1. Much more detailed stratigraphic sections are given by Grohskopf (1955), Koenig (1961), and Cushing and others (1964). The table shows that the area has three major aquifers (water-bearing units), the alluvium, the Wilcox Group, and the McNairy Formation, although some investigators (Cushing and others, 1970) list more.

The alluvium covers about 3,600 mi^2, or 90 percent of the project area. This alluvium, which was laid down by the ancestral Mississippi and Ohio Rivers, may reach a maximum thickness in excess of 250 ft. The alluvium is the only aquifer that is used for irrigation in the area. This aquifer also supplies most of the domestic water and much of the municipal and industrial waters. Although most irrigation wells tapping the alluvium yield about 1,000 gal/min, yields of more than 3,000 gal/min have been reported. This aquifer is so prolific that most irrigation wells are only 70 to 100 ft deep, even though the alluvium is generally much thicker.

The Wilcox Group underlies about 2,200 mi^2 of the area. This group crops out, or is exposed at the surface, over about 100 mi^2 on Crowleys Ridge and Benton Hills. This group consists of up to 1,400 ft of unconsolidated or loosely consolidated sand and clay. This aquifer, which is reported to yield more than 1,500 gal/min in some areas, supplies many municipal systems.

Table 1.--Generalized stratigraphic section for the Mississippi embayment of southeastern Missouri

[The stratigraphic nomenclature used in this report is that of the Missouri Division of Geology and Land Survey and differs somewhat from the current usage of the U.S. Geological Survey]

Era	System	Group	Formation	Maximum thickness expected (ft)	Est. age of time boundaries (m.y.)	Extent	Lithologic character	Hydrologic character
Cenozoic	Quaternary		Alluvium	250	0	Underlies entire lowland area.	Gravel, sand, silt, and clay.	Chief aquifer in the area. May yield 3,000 gal/min to wells in some localities.
			Loess	35	2	Covers Crowleys Ridge, Benton Hills, and uplands.	Tan to brown silt. May contain some clay.	Occurs above the water table.
			Terrace Gravel	60	(?)		Gravel, cobbles, some clay.	
	Tertiary	Wilcox		1,400	40 54	Crops out on Crowleys Ridge and Benton Hills. Underlies all of area south and east of line from Campbell to Charter Oak to Sikeston to Lusk.	Sand, some clay. Contains thin beds of lignite.	A major aquifer used chiefly for municipal supply. Known to yield 1,500 gal/min in favorable localities. May contain at least two aquifers with separate potentiometric surfaces.
		Midway	Porters Creek Clay	650	54	Crops out on Crowleys Ridge and Benton Hills. Underlies all of area south and east of a line from Neelyville to Bloomfield to Commerce.	Clay, light grey when dry, but dark grey when wet.	Does not yield significant quantities of water to wells. Acts as barriers to ground-water movement.
			Clayton Formation	30	65		Calcareous, glauconitic sand and clay to fossiliferous limestone.	
Mesozoic	Cretaceous		Owl Creek Formation	100	65	Crops out on Crowleys Ridge and Benton Hills. Underlies entire area except within about 10 mi of Ozarks.	Bluish-gray to brown sandy clay.	Generally impedes the flow of ground water.
			McNairy Formation	600 (combined thickness)			Sand, sandy clay, and clay; Nonmarine at outcrop, but marine in deep part of the embayment.	A significant aquifer widely used for municipal supplies. High heads make this aquifer attractive but excessive mineralization and high temperatures limit its use in some areas.
			Pre-McNairy Cretaceous Beds		100	Present only in deeper parts of the embayment.	Sand, chalk, marl, clay, and limestone.	
Paleozoic	Numerous formations. For description, see Koenig, J. W. (ed), 1961, The stratigraphic succession in Missouri.			>2,680	375 570	Crops out on Crowleys Ridge, Hickory Ridge, and Benton Hills. Underlies entire area.	Limestone, sandstone, and dolomite	Used for municipal supplies close to the Ozarks. Would probably yield large amounts of water in other areas but this water may be highly mineralized in some areas.

The Wilcox Group is the primary aquifer that is used for municipal supplies in the southern part of the area near the Mississippi River. This group contains both the Claiborne and Wilcox aquifers discussed in Arkansas reports (Ryling, 1960), and several aquifers discussed in the Mississippi embayment reports (Hosman and others, 1968).

The McNairy Formation, which is locally called the "Ripley Sand," underlies about 3,000 mi^2 of the project area and crops out over about 125 mi^2 on Crowleys Ridge and Benton Hills. This formation, which consists of sand, sandy clay, and clay, is reported to yield more than 700 gal/min in some areas (Boswell and others, 1965). The high artesian pressure, the very low hardness, and low iron concentration of the water makes this aquifer attractive for municipal supplies even though this aquifer may occur at considerable depths.

Various Paleozoic formations are also aquifers; these are used primarily in the northern part of the area. These formations were not studied in detail in the present project because they are used in only a small part of the area.

IRRIGATION WELLS

One of the primary purposes of the project was to determine the extent of irrigation in the Mississippi embayment of southeastern Missouri. Early in the project, as many irrigation wells as possible were located. From the fall of 1974 through the summer of 1976, field personnel located irrigation wells in the area. These locations were frequently based on information obtained from landowners, irrigators, and agricultural experts in the area, but the locations were generally field checked by visiting the sites.

Although many irrigation wells were found, it was impossible to locate every irrigation well; an estimated 25 percent of the wells in the area were not located. In some areas this percentage may be larger, whereas in other areas nearly every irrigation well was probably located. In addition to wells not located during the initial inventory, several hundred new wells were drilled each year. Table 2 lists 3,091 irrigation wells that were located during the well inventory. Figure 2 is a map showing the irrigation wells listed in table 2. Some wells tabulated and mapped are probably already destroyed, as wells are frequently pulled and new wells constructed. It was estimated that by the end of 1977, there were nearly 4,500 irrigation wells in the Mississippi embayment of southeastern Missouri.

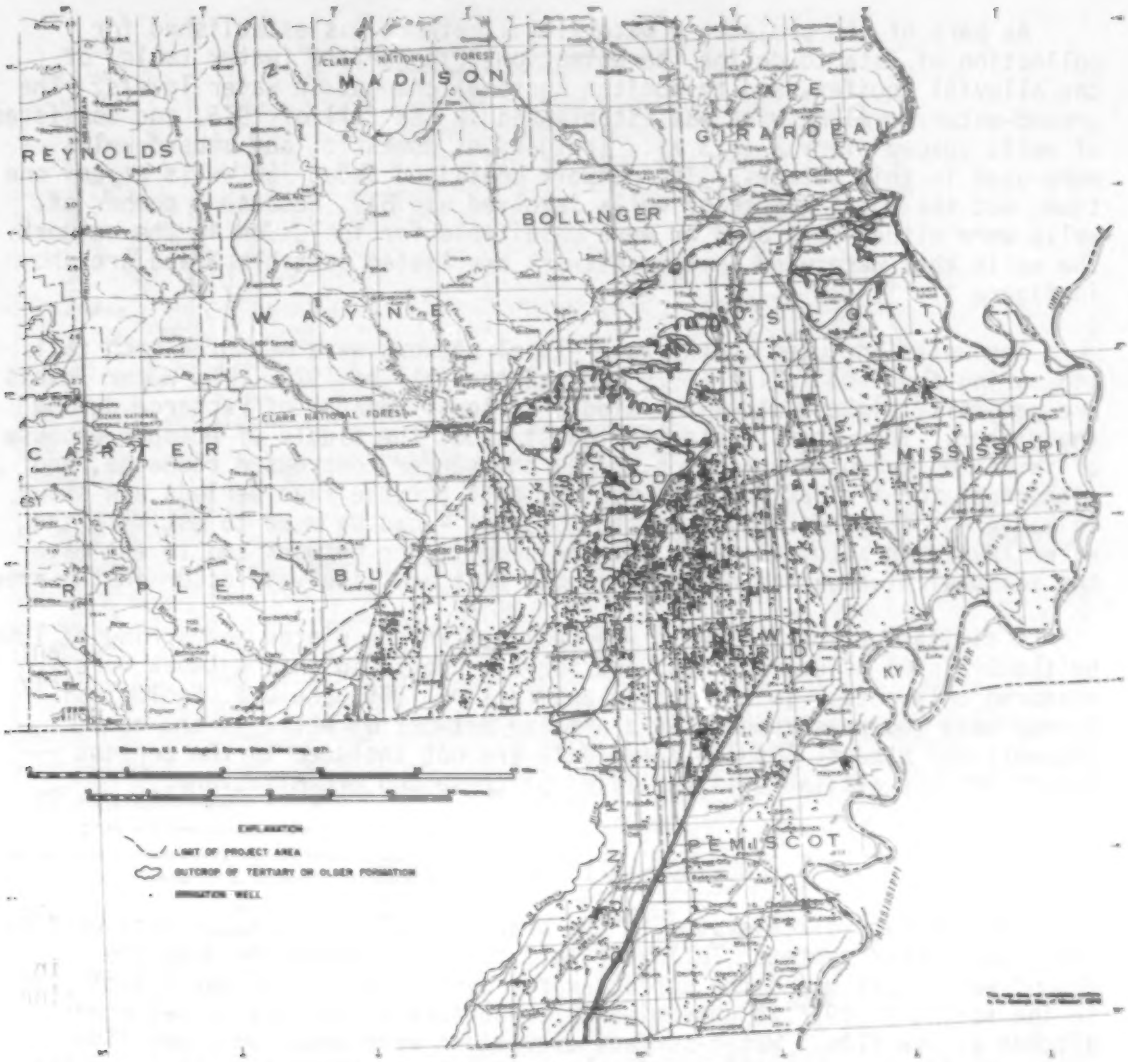

Figure 2.—Irrigated irrigation wells in southeastern Missouri.

GROUND-WATER-LEVEL NETWORK

As part of the project, a water-level network was established for collection of data to define the potentiometric surface (water table) of the alluvial aquifer, and to monitor seasonal changes in water levels. The ground-water-level network was established in the fall of 1975, and consisted of wells spaced every 2 to 3 mi. Irrigation, domestic, and unused wells were used in this network. The network contained about 750 wells at any one time, but the total number of wells involved was 819, because a number of wells were either destroyed or were unsuitable for inclusion in the network. The wells that were used in this network are listed in table 3 and are shown in figure 3.

The wells included in the water-level network were measured each fall and spring from the fall of 1975 through the fall of 1977. The water levels are generally highest about the middle of April because of recharge during the winter. The water levels are lowest about the middle of October because of increased evapotranspiration during the summer, decreased recharge, and withdrawal for irrigation. The measurements for the five periods are shown in table 4. The information in tables 3 and 4 can be used to estimate the water levels in alluvial wells not included in the network and to estimate the seasonal fluctuation of water levels that are likely to occur in the area.

A similar network of wells was measured in the winter and spring of 1956 by the Division of Geology and Land Survey. Wells in this network were measured only once. In the spring and fall of 1965, the U.S. Geological Survey made two measurements in a similar network of wells in the area (Boswell and others, 1968). These data are not included in the present report but are available in the files of these two organizations.

SURFACE-WATER-LEVEL NETWORK

The drainage-ditch system in the area probably has a major influence on the ground-water system. To investigate the relationship between the ground-water system and the surface-water system, a network was established in the spring of 1976 to determine water-surface elevations in selected ditches at low flow. Water-surface elevations were measured along five east-west lines and at intermediate points between these five lines on the major drainage ditches and rivers in the area. The five lines are Cardwell to Acorn Corner in Dunklin and Pemiscot Counties; Naylor to Portageville in Ripley, Butler, Dunklin, and Pemiscot Counties; Poplar Bluff to Thirty-Four Corners in Butler, Stoddard, New Madrid, and Mississippi Counties; Aquilla to Lusk in Stoddard and Scott Counties; and Toga to Randles in Stoddard and Cape Girardeau Counties.

Water-surface elevations were measured during the spring and fall in 1976 and 1977, at the same time that ground-water levels were measured. At each surface-water site a reference point was established and water levels were measured from the reference point. These reference points are generally

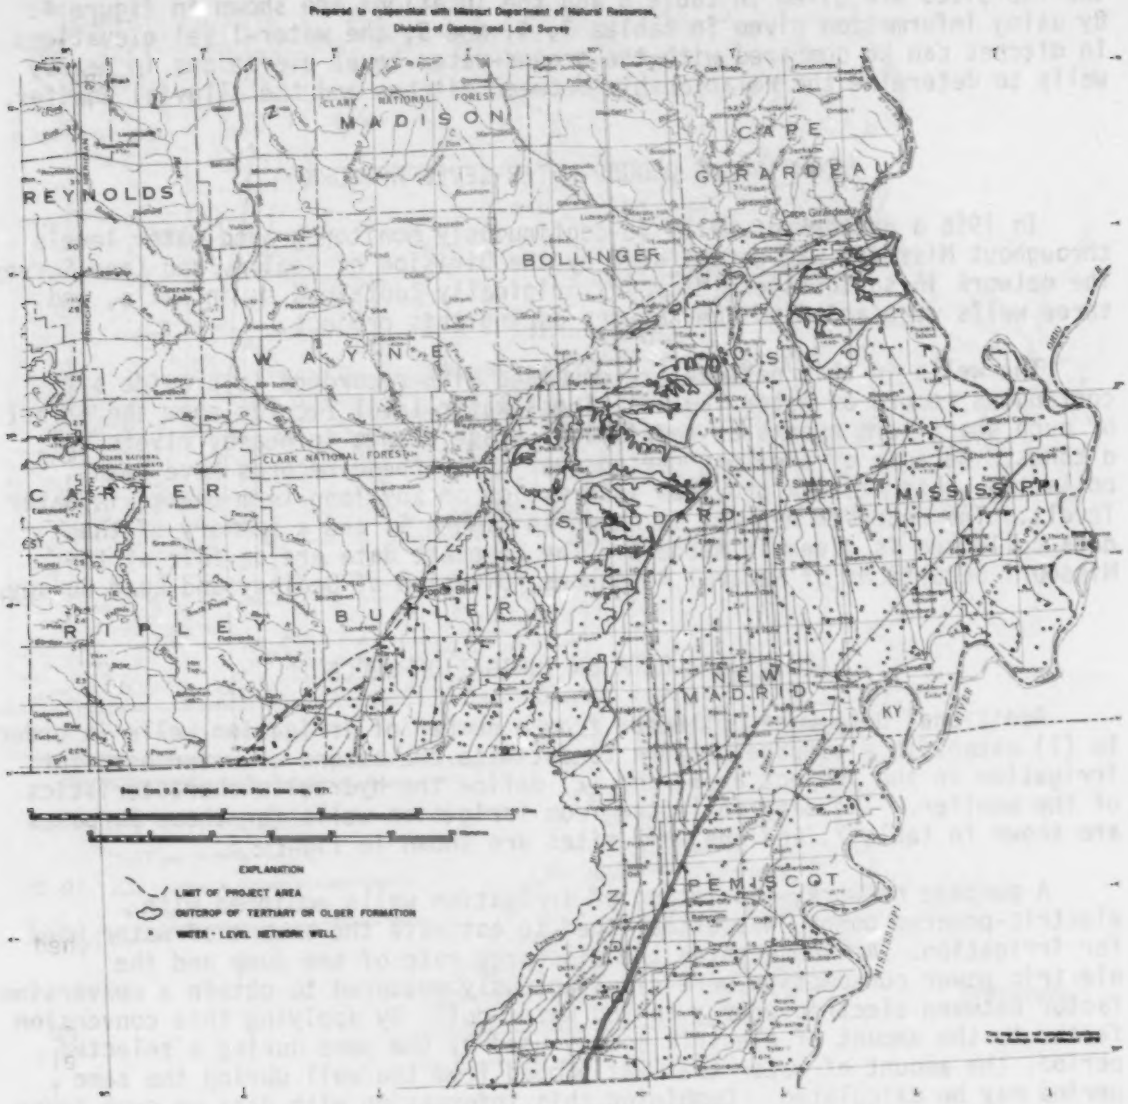

Figure 3.--Ground-water-level network in southeastern Missouri.

marked on the top rail of a bridge. A description of these reference points is available in the files of the U.S. Geological Survey. Measurements from the 133 sites are given in table 5 and the locations are shown in figure 4. By using information given in tables 3, 4, and 5, the water-level elevations in ditches can be compared with the ground-water-level elevations in nearby wells to determine the relationship between ditches and the alluvial aquifer.

CONTINUOUS GROUND-WATER-LEVEL NETWORK

In 1956 a network of wells to continuously monitor ground-water levels throughout Missouri was established by the Division of Geology and Land Survey. The network in southeastern Missouri originally contained seven wells, and three wells were added to the network during this project.

The wells in this network are equipped with recorders to provide a continuous record of water levels. These water-level records show the effect of such short-term events as rainfall or stage change in nearby rivers or ditches. Because of the long period over which these records have been collected, this network provides information on any long-term change in water levels. The recorder network is shown in figure 5, and a summary of the data collected is given in table 6. The complete data are on file at the Missouri Department of Natural Resources, Division of Geology and Land Survey.

ADDITIONAL DATA ON IRRIGATION WELLS

Additional data were collected from a number of irrigation wells in order to (1) establish a pumpage network to estimate the amount of water used for irrigation in the project area, and (2) define the hydraulic characteristics of the aquifer. The data collected from irrigation wells for these purposes are shown in table 7, and the well sites are shown in figure 6.

A pumpage network, consisting of irrigation wells equipped with electric-powered pumps, was established to estimate the amount of water used for irrigation. At these sites the discharge rate of the pump and the electric power consumption were simultaneously measured to obtain a conversion factor between electric energy in and water out. By applying this conversion factor to the amount of electric energy used by the pump during a selected period, the amount of water that was pumped from the well during the same period may be calculated. Combining this information with data on crop types and acreages, estimates of water use for irrigation can be made.

The other purpose for collecting additional data from irrigation wells was to estimate the hydraulic characteristics of the alluvial aquifer. At these wells, the discharge of the pump and the drawdown in the pumped well were simultaneously measured. Aquifer tests were made at some wells to determine the hydraulic characteristics of the aquifer.

Figure 4.—Surface-water-level network in southeastern Missouri.

Figure 5.--- Sites at which continuous ground-water-level data are collected in southeastern Missouri.

Figure 6.--- Irrigation wells where additional data were collected.

Although most of the data items collected from irrigation wells are self-explanatory, a few items are worthy of further discussion.

Two methods were used to measure the discharge of the wells. The first method, commonly called the trajectory method, requires measuring the inside diameter of the discharge pipe and the velocity of the water in the discharge pipe. This method is simple and fairly accurate and requires only a yardstick, plumb bob, and a set of tables. The trajectory method can only be used on open-ended pipes such as those that discharge into rice ponds. This method, which is illustrated in "Water Well Handbook" (Anderson, 1971, p. 56), involves deviation of the water stream from the axis of the pipe. The second method, called the volumetric method, was used to measure the discharge from gated irrigation pipe. The discharge from at least 10 percent of the open gates (and at least 10 gates) was calculated by measuring the amount of time it took to fill a calibrated bucket from each gate. The average discharge from all gates was then calculated, the number of open gates counted, and the total discharge from the well computed.

Specific conductance is a measure of the ability of water to conduct an electric current and is expressed in µmho/cm at 25°C (micromhos per centimeter at 25 degrees Celsius). Specific conductance is related to the number and type of chemical ions in solution and is a measure of the dissolved-solids concentration of the water. Commonly the dissolved-solids concentration, in milligrams per liter (mg/L), is about 55 to 75 percent of the specific conductance, in µmho/cm at 25°C (Hem, 1970).

The pH is a measure of the acidity or alkalinity of water. A pH of 7.0 indicates that the water is neutral; a pH below 7.0 indicates that the water is acidic; and a pH above 7.0 indicates that the water is alkaline. The pH scale is a logarithmic scale, which means that a unit change in pH indicates a 10-fold change in acidity or alkalinity.

The kW_i is the instantaneous rate of electric energy consumption of the pump in kilowatts. This rate is calculated from the time required for the disc on the electric meter to make 10 revolutions. This kW_i will be very near the kilowatt demand shown on some types of electric meters in use in the area. Kilowatts can be converted to horsepower by multiplying kilowatts by 1.34. The horsepower so obtained should be very near the rated horsepower of the motor, if the motor is in good working conditon.

The overall efficiency or "wire-to-water" efficiency of a pumping plant can be calculated using the data found in table 7. The kW_i is the rate of energy input to the system. The yield multiplied by the lift is the rate of energy output from the system. The lift is the pumping-water level plus any additional lift above land surface or lift needed to overcome friction

losses. The formula for computing efficiency, in percent, is:

$$\text{Efficiency} = 0.01886 \left(\frac{\text{Yield}}{kW_i}\right) (\text{pumping level} + \text{added lift}),$$

where the yield is in gallons per minute, kW_i is in kilowatts, and the pumping level and added lift are in feet. The overall efficiency of pumping plants generally ranges from 20 to 80 percent, but all of the efficiencies calculated from the data in table 7 fall in the lower one-half of this range.

The KA is a conversion factor to convert electric energy used (in kilowatt hours) to water pumped (in acre-feet). By obtaining the kilowatt hours used by the pump from either the power meter or the utility bill and dividing this number by the KA, the pumpage in acre-feet can be calculated. The KA, which is dependent on such things as the pumping level, the pressure in the discharge pipe, and the condition of the pumping unit, is not constant but will vary somewhat over time. However, this variation is not too large to preclude a reasonable estimate of the pumpage.

GEOLOGIC DATA

The geologic data given in this report were obtained from the geologic-log files of the Missouri Department of Natural Resources, Division of Geology and Land Survey, and from published sources (Grohskopf, 1955, and Farrar and McManamy, 1937).

The geologic data listed in this report (table 8) are not extremely detailed. Formations were occasionally grouped together, even though individual formation contacts may have been available on the original logs. The Paleozoic units are shown in table 8 even though these units are not shown in the generalized stratigraphic section (table 1). The location of the wells for which geologic data are given is shown in figure 7.

MUNICIPAL AND PUBLIC WATER-SUPPLY DISTRICT WELLS

A summary of data for selected municipal wells in the Southeast Lowlands is shown in table 9. These data were generally reported by either the drillers or the municipalities. Not all of the wells shown in this table are currently in use, nor does this table represent all of the municipal wells in the area. Only those wells where fairly complete records were available are included. Another source of information on public water supplies, both ground-water and surface-water supplies, is available in Census of Public Water Supplies in Missouri (1975).

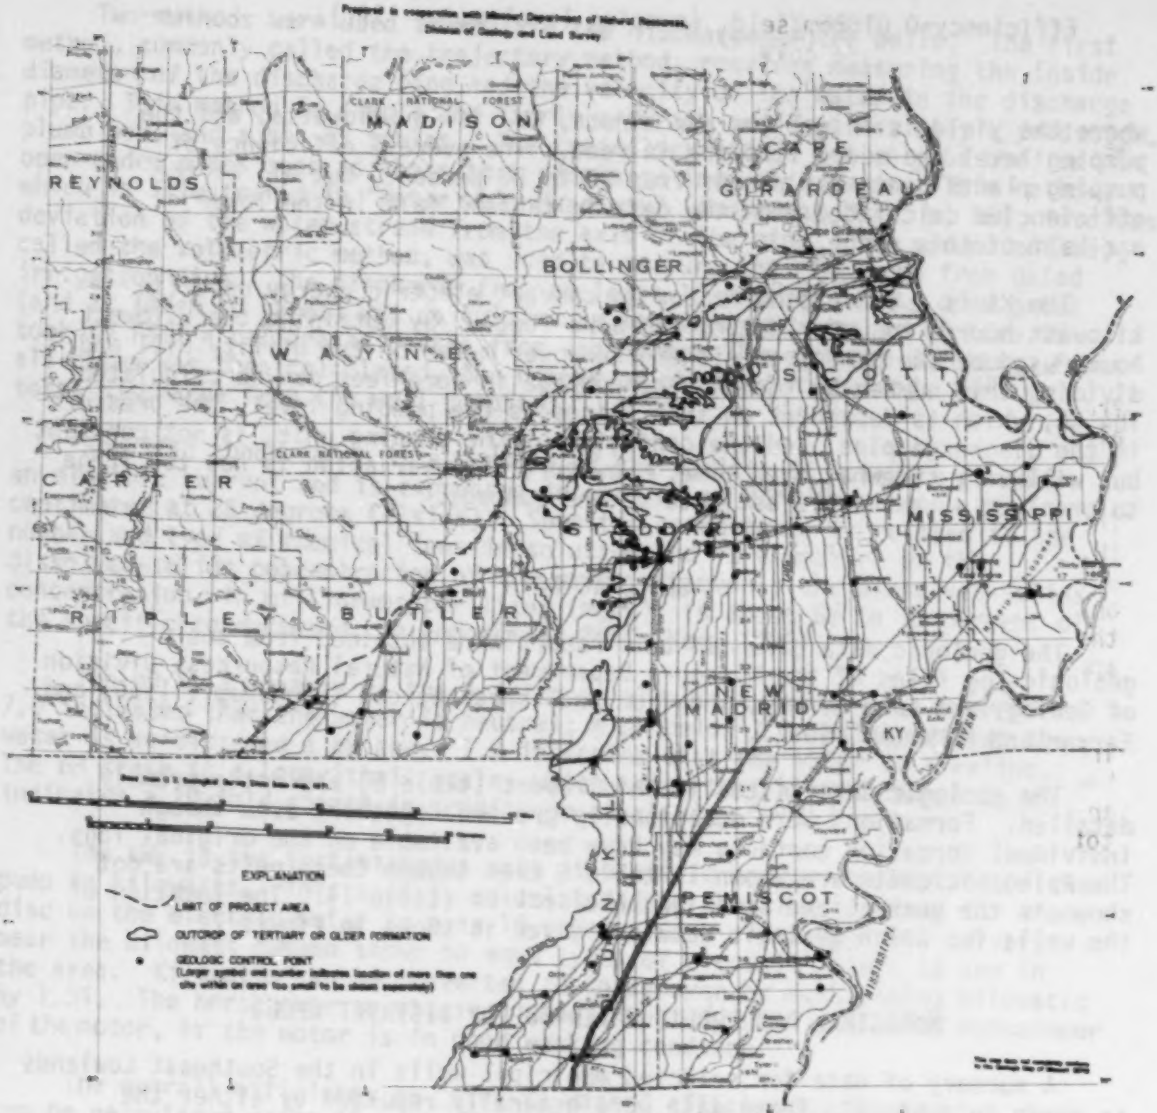

Figure 2.— Sites where geologic data are presented.

WATER-QUALITY DATA

Water samples from selected wells and drainage ditches in southeastern Missouri were collected and analyzed by the Division of Geology and Land Survey. In addition, their files contain the results of analyses made on water samples collected over a number of years from many other wells in the area. The results of all these analyses are shown in table 10, and the locations of the wells sampled are shown in figure 8. Many refinements have been made in both sampling and sample-handling techniques and in analytical techniques and methodology over the years in order to obtain data that are more representative of water in the aquifers. Therefore, some differences in the data shown in table 10 may be due to changes in sample collection and analytical techniques rather than changes in the quality of water samples. For instance, some analyses show a pH of less than 8.3, but show carbonate (CO_3) in the analysis. This probably results from pH and carbonate and bicarbonate determinations being made on separate aliquots of water and at different times.

Public-health limits for two constituents are listed in table 10. These standards, National Interim Primary Drinking Water Regulations (U.S. Environmental Protection Agency, 1975), are for nitrate (as N) which should be less than 10 mg/L, and for fluoride, whose limit depends on the average annual air temperature but ranges from 1.6 to 1.8 mg/L in the Mississippi embayment of Missouri. The fluoride concentration limit applies only to community water systems.

For domestic use, three other constituents are also of interest; high iron or manganese concentrations stain laundry and affect the taste of beverages; total hardness will affect the action of soap and will leave an encrustation when heated. The classification of water according to total hardness is:

0 to 60 mg/L	Soft
61 to 120 mg/L	Medium hard
121 to 180 mg/L	Hard
>180 mg/L	Very hard

SUMMARY

The 4,000 mi^2 Mississippi embayment of southeastern Missouri is a productive agricultural area that is presently undergoing rapid irrigation development. Although three major aquifers are available in most of the area, the alluvial aquifer provides most of the ground water that is withdrawn.

This report provides well owners, well drillers, water users, and potential irrigators with the hydrologic data collected during a cooperative study between the Missouri Department of Natural Resources, Division of
